Agenda

SAS Enterprise Miner

Best practices for creating a predictive model

- Background and General Guidance
- Data Construction
- Model Development and Delivery

Best practices to help you meet and exceed your goals

Faster model development
More *useful* models
Superior models

Disclaimers

- The choice of “Best Practices” is highly subjective.
- Certain suggested practices may not be suitable for a particular situation.
- It is the responsibility of a data mining practitioner to critically evaluate methods and select the best method for a particular situation.
- This presentation represents the opinions of those who contributed.

Background

Analytics Cycle and the modeling Process

Why use Predictive Modeling?

To Turn increasing amounts of raw data into useful information

Descriptive

Clustering (Segmentation)

grouping together similar people, things, events

- Transactions that are likely to be fraudulent, Customers that are likely to have similar behaviors.

Associations

affinity, or how frequently things occur together, and sometimes in what order

- Customers who purchase product A also purchase product B

Predictive Models

Classification models

predict class membership

- 0 or 1: 1 if person responded; 0 otherwise
- Low, Medium, High: a customer's likeliness to respond

Regression models

predict a number

- \$217.56 – Total profit, expense, cost for a customer
- 37 – The number of months before a customer churns

The Goal? Scoring!

- Scoring is the act of applying what we've learned from data mining to **new cases**.
- Keep this goal in mind and use it to help formulate the questions and the data needed for data mining and scoring.

Example

Developing a Classification Model

- Models are developed using historical data in which the **behavior is observed or known**.

 Indicates the behavior was observed in this subject

- Information about each subject, in this case an individual, is used as inputs to the model to see how well the model can distinguish between the people who exhibit the behavior and those who do not. For example, age, gender, previous behaviors, etc.

Why?

- Consider a group of subjects whose relevant behavior is unknown.
- The same information is available for each of these subjects (age, gender, etc.) as is available for the individuals with known behavior.
- We would like to know **which individuals are most likely to have the relevant behavior.**

How?

- The output of a predictive classification model is typically an equation. Models are applied to new cases to calculate the **predicted behavior** through a process called **scoring**.
- **Scoring**, using the equation, calculates each subject's *likelihood to have the relevant behavior*. (It also calculates the likelihood to *not* have the behavior.)

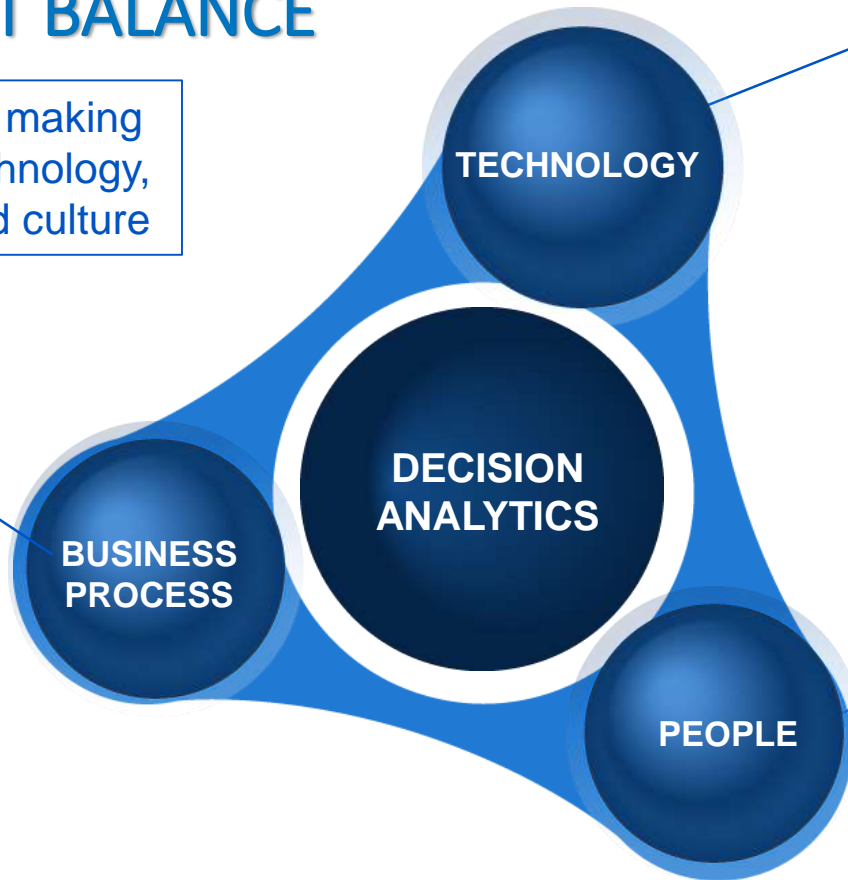

General Guidance

Analytics Cycle and the Modeling Process

ITS ALL ABOUT BALANCE

Fact-based decision making requires the right technology, talent, processes and culture

- Continuous Process Improvement
- Planning
- Project methodology
- Standards

- BI reporting
- Web portals / dashboards
- Information management
- Problem-specific business solutions
- Predictive analytics
- Hardware

- Vision & Leadership
- Team composition
- Enterprise authority

Lifecycle Best Practice

Involve all the relevant people/roles

BUSINESS MANAGER

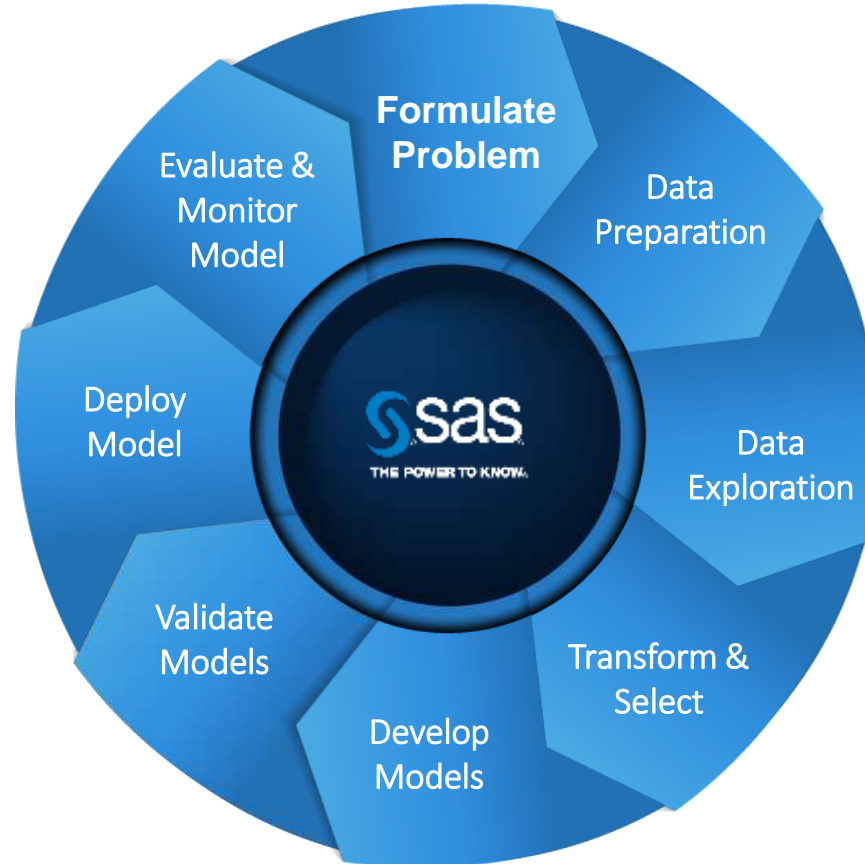

Domain Expert
Makes Decisions
Evaluates Processes & ROI

BUSINESS ANALYST

Data Exploration
Data Visualization
Report Creation

DATA MINER DATA SCIENTIST

Exploratory Analysis
Descriptive Segmentation
Predictive Modeling
Model Validation & Registration

IT/SYSTEMS MANAGEMENT

Model Validation
Model Deployment
Model Monitoring
Data Preparation

Use the Technology and Method the Fits the Job

Every tool and method has advantages and disadvantages.

Whenever possible, select the tool or method that balances *long-term* goals for the *entire* process.

Best Practice

Begin with the End in Mind

Begin with the End in Mind

- **What** is the overarching strategic objective/initiative?
- **How** will the model be used?
- **How** will it be put into production?
- **Who** will be affected by the use of the model?
- **Who** needs to be convinced of the value of the model?
- **When** will the model be used?

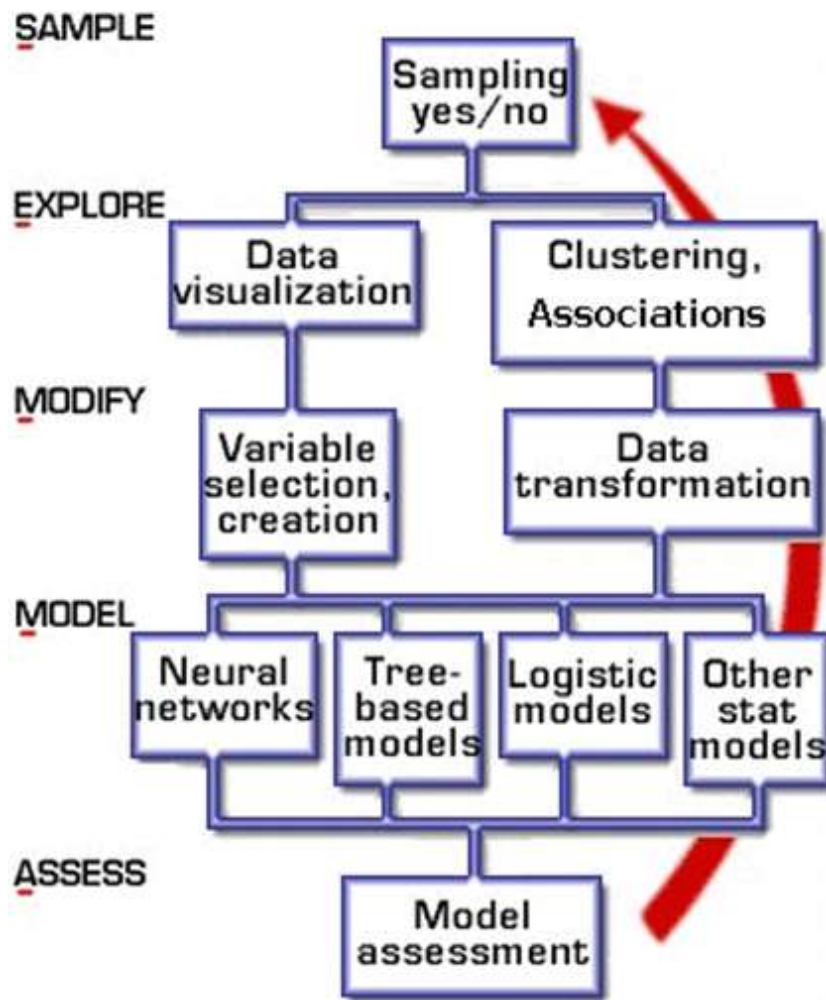

Best Practices

Business considerations Before you model

- Thoroughly understand the business/marketing objectives
- Detail the precise (planned) usage for the output
- Define the target variable (the outcome being modeled / predicted)
- Formulate a theoretical model: $Y = f(X_1, X_2, \dots)$ ← fill-in the likely X's

BEST PRACTICE

SEMMA Process for Model Development

Best Practice

Modeling Approach

1. **Sample** → training set(s), validation set(s), holdout test set
2. **Explore** → min, max, mean, median, missing values, levels (categorical cardinality)
3. **Modify** → filtering outliers, reducing cardinality, correcting multicollinearity, imputations, non-linear transformations

Best Practice Modeling Approach

- 
4. **Model** → variable selection, various model formulations, iterative cycle, insights & client reviews
 5. **Assess** → performance criteria and review

Best Practice

Modeling approach (Continued)

6. Final Assessment & Testing
7. Profile characteristics & indicators
8. Document results
9. Prepare (production-ready) data collection and score code
10. Monitor model performance

Developing the Data

Determining Data

Best Practices

Technical Considerations Before Modeling

- Brainstorm all potential input data elements
- Identify source systems, specific data fields, availability/priority/level-of-effort of data
- Finalize data to be collected

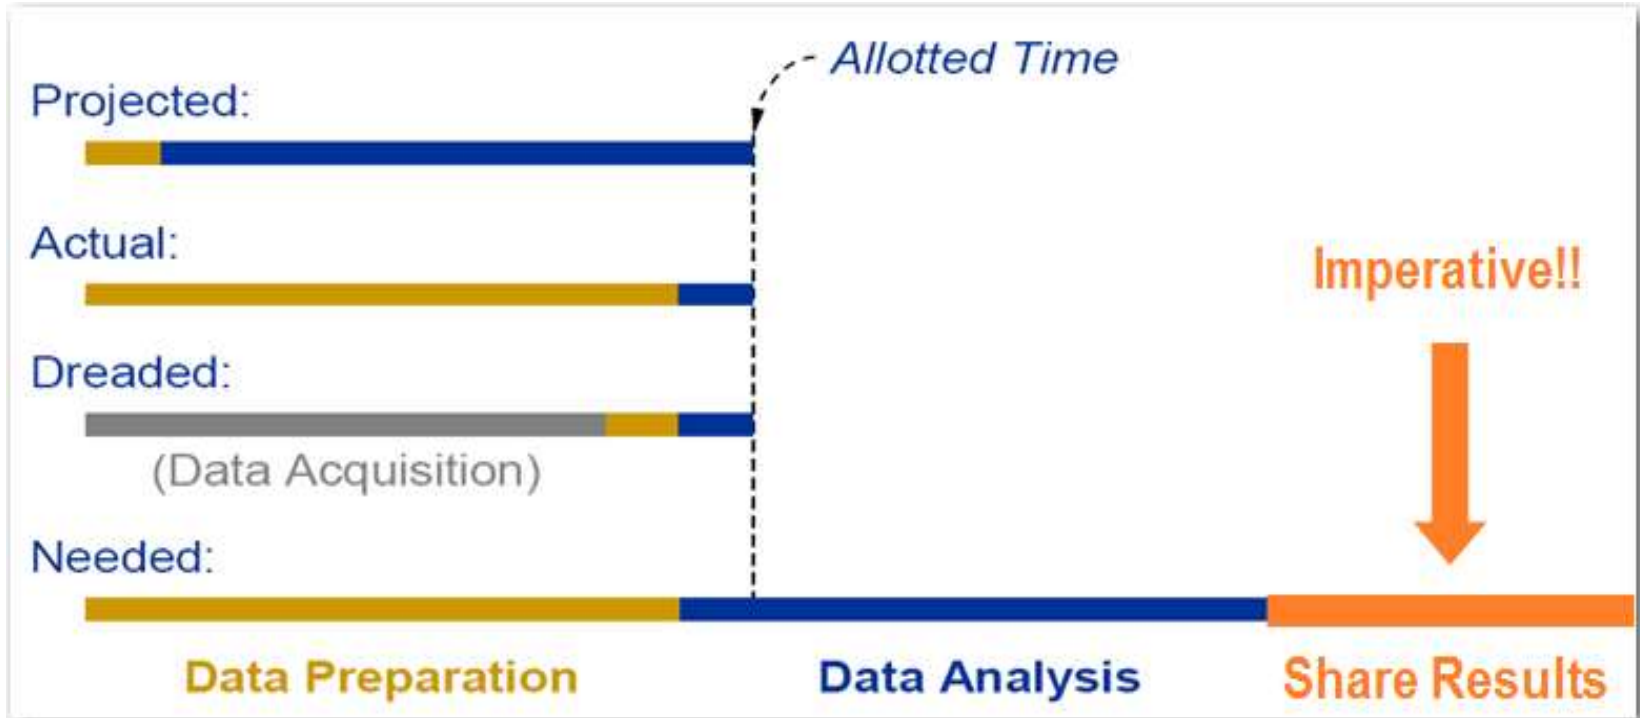

Best Practices

Technical Considerations Before Modeling

- Formulate structure and layout of modeling dataset to be built
- Devil-in-the-details: filters, timeframe of history, etc...
- Build modeling dataset

Best Practice

Allow sufficient time for all aspects

Sample

- (Over) Sampling
- Partitioning
- Decisioning

Sample

Sample

To Sample or Not?

- Sampling is a valuable tool that can be used to great effect.
- If computing resources are no object, it's possible to use all data.
- When resource constrained, try increasing sample sizes as model development progresses.
- When model is nearly finalized, try different seeds for samples to ensure model stability.

Sample

What About Oversampling?

- **It depends.**
- Frequently one needs to oversample in order to allow algorithm(s) to identify effect, especially with rare targets.
- Only oversample as much as you need to in order to obtain a model that makes sense from a business perspective. This is **highly subjective.**

Adjusting for Oversampling

Why?

- Prediction estimates reflect target proportions in the training sample, not the population from which the sample was drawn.
- Score Rankings plots are inaccurate and misleading,
- Decision-based statistics related to misclassification or accuracy misrepresent the model performance on the population.

Adjusting for Oversampling Prior Probabilities

Before

Decision Processing - DONOR_RAW_DATA

Targets Prior Probabilities Decisions Decision Weights

Do you want to enter new prior probabilities?

Yes No

- After fitting model
 - Decision Node

Partitioning

SAMPLE

Data Partitioning

PARTITION	ROLE
Training	Used to fit the model
Validation	Used to validate the model and prevent over-fitting
Test	Used to provide unbiased estimate of model performance

Sample

SAMPLE: Data Partitioning

WHAT IS OPTIMAL PARTITION?

Best Practice

SAMPLE: Data Partitioning

WHAT IS OPTIMAL PARTITION?

Best Practice

Sample: Data Partitioning

**WHAT IS OPTIMAL
PARTITION?**

Sample

Data Partitioning Considerations

- How much data is available?
- Is an unbiased measure of model performance required?
 - Should test data be in-sample or out-of-sample?
- How many test samples are needed? (e.g. different time periods, different geographies, etc.)
 - When should test data be used in the process?

Data Partitioning

- Percentages: frequently used percentages are 50/50/0, 60/40/0 and 70/30/0 with a completely separate Test partition.
- Do not bring Test data into process until model is complete. It should not influence modeling process, merely used to report performance.
- Multiple Test data can be used – consider how model will be deployed and create representative samples.

Decisioning

Weighting Your Decisions

- Expected Profit
- Decision Boundaries

Understanding expected profit

- Consider this game
 - Flip a fair coin one time
 - If it is heads, you win \$10.00
 - Cost of playing one time is \$1.00

Do you want to play this game?

Understanding expected profit

- Consider this game
 - Flip a fair coin one time
 - If it is heads, you win \$10.00
 - Cost of playing one time is \$1.00

$$\begin{aligned} E(\textit{Profit}) &= 0.5 * (10 - 1) + 0.5 * (-1) \\ &= 4.50 + (-0.50) = 4.00 \end{aligned}$$

Decision Theory

What is it?

- Decision Theory is an aid to making optimal decisions from predictive models.
- Each target outcome is matched to a particular decision or course of action.
- A profit value is assigned to both correct and incorrect outcome and decision combinations.
- The best model is selected based on maximizing profit or minimizing cost.

Decisions

Combining the Decisions with Weights

Decision Processing - DONOR_RAW_DATA

Targets Prior Probabilities **Decisions** Decision Weights

Selecting Target

Choosing your target

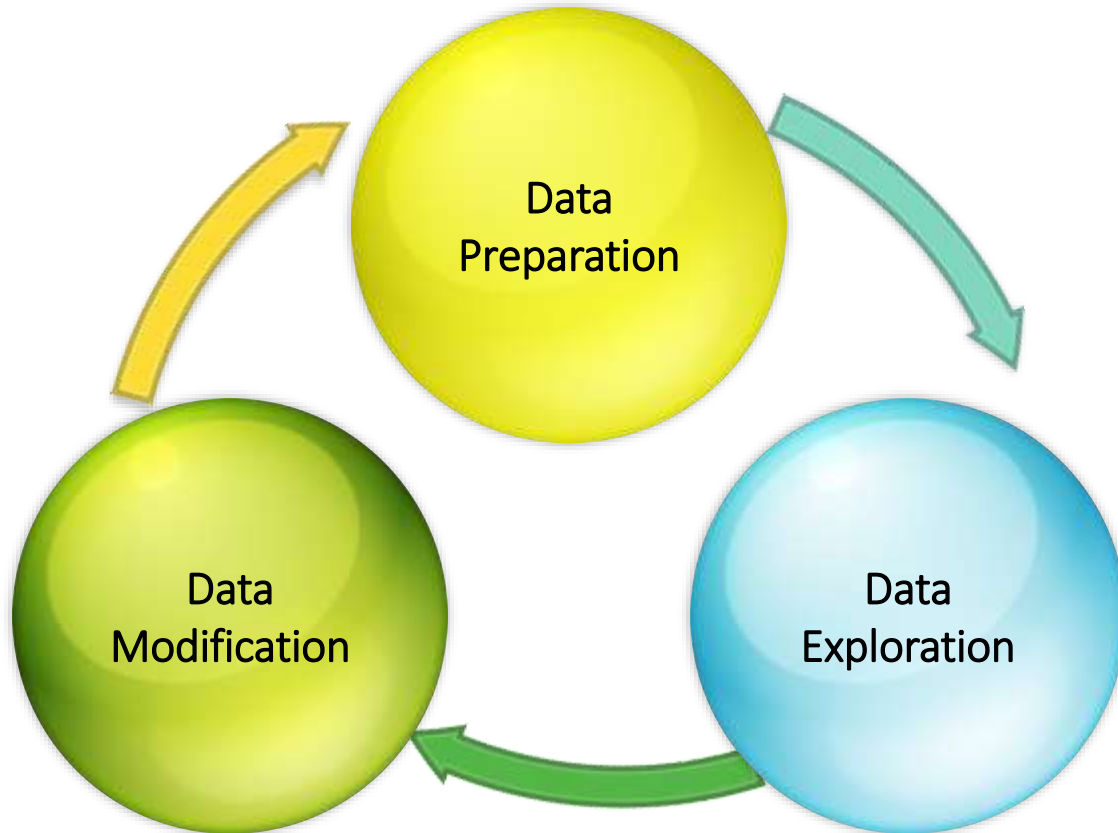

- Choosing the Target
- Response vs. Propensity
- Number of Models

Preparing Data

EXPLORE & MODIFY

Iterative Relationship with Data Preparation

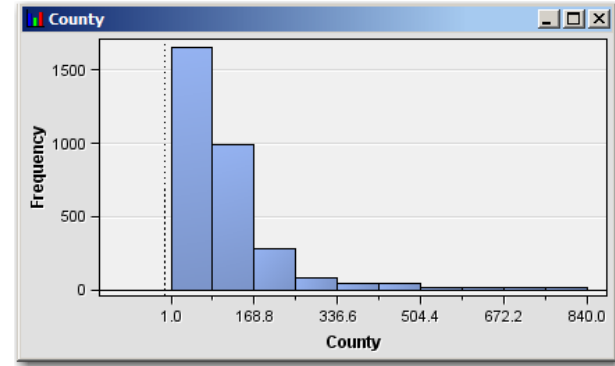

Explore & Modify: Getting the Most out of Data

- Once you have an analytics-ready table:
 - Examine *Categorical* Variables
 - Examine *Continuous* Variables
 - Explore *Missing* Values
 - *Cluster* Variables

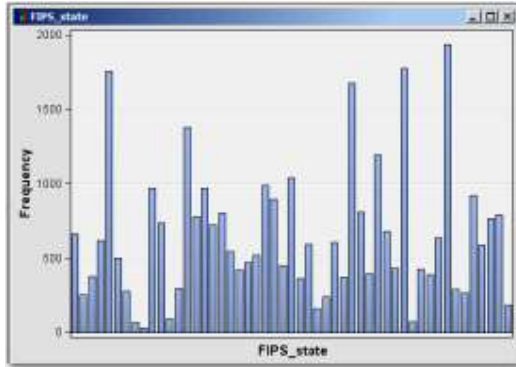

Explore & Modify Categorical Variables

Explore & Modify Categorical Variables

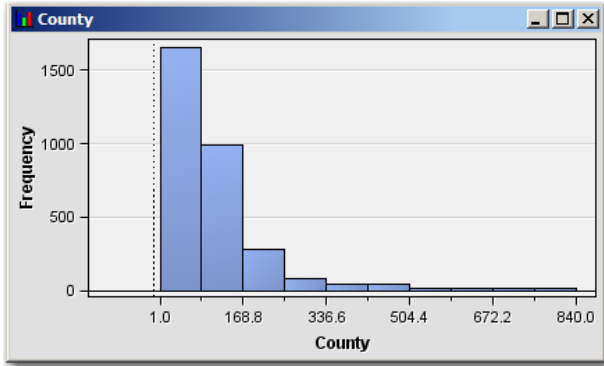

Too many overall values

- Is there a higher level of a hierarchy that could be used instead?
- Can this be represented by a group of variables with fewer values?
 - Example: **Zip Codes** alternatives
 - MSA or state
 - Geographic, demographic, economic status

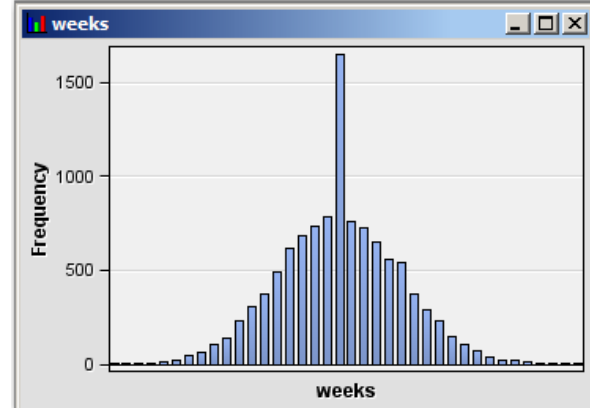

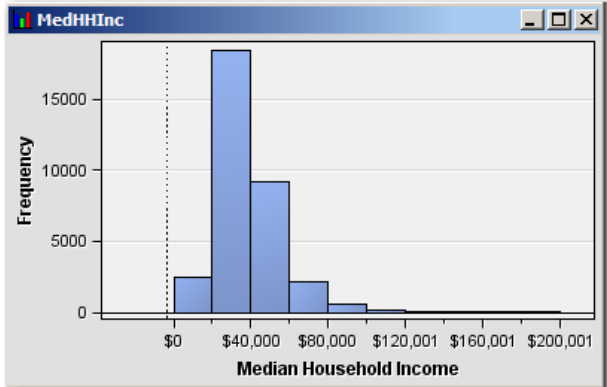

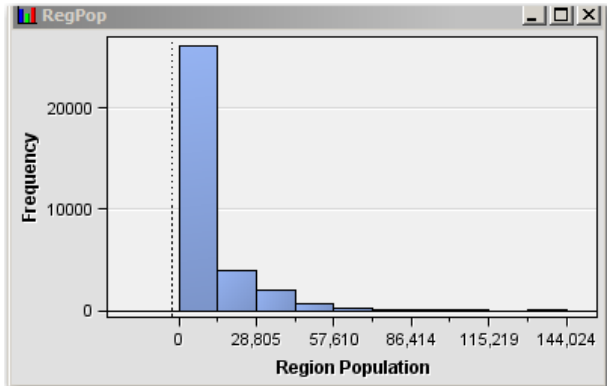

Explore & Modify Categorical Variables

Levels that rarely occur

- Group infrequently occurring values together as “other”
- Judiciously combine a less frequently occurring level with a more frequent one where it makes business sense
- Consider a less granular level of a hierarchy

Explore & Modify Continuous Variables

Explore & Modify Continuous Variables

Extremely skewed predictors

- Consider transformations that stabilize variance and generate more support across the range of values
- Consider binning transformation with appropriate number of bins to enable each portion of the ranges to be weighed appropriately

Explore & Modify Continuous Variables

Spike and a Distribution

- Consider creating two variables from the original
 - Flag variable to indicate whether value is in the spike
 - Variable from the values of the predictors in the distribution
 - Set values at spike to missing and impute

Explore & Modify Continuous Variables

One level that almost always occurs

- Consider a new variable that is a binned version
- Consider whether it's sufficient to create only a binary indicator

Explore & Modify Missing Data

- *Why* is data missing?
- Are there *patterns* to the missing data within or across variables?
- *Imputation methods* to consider
- *Indicator variables*

Explore & Modify Variables for Clustering

- There is no single answer for clusters
- Design clusters and profiles around themes using smaller set of related variables

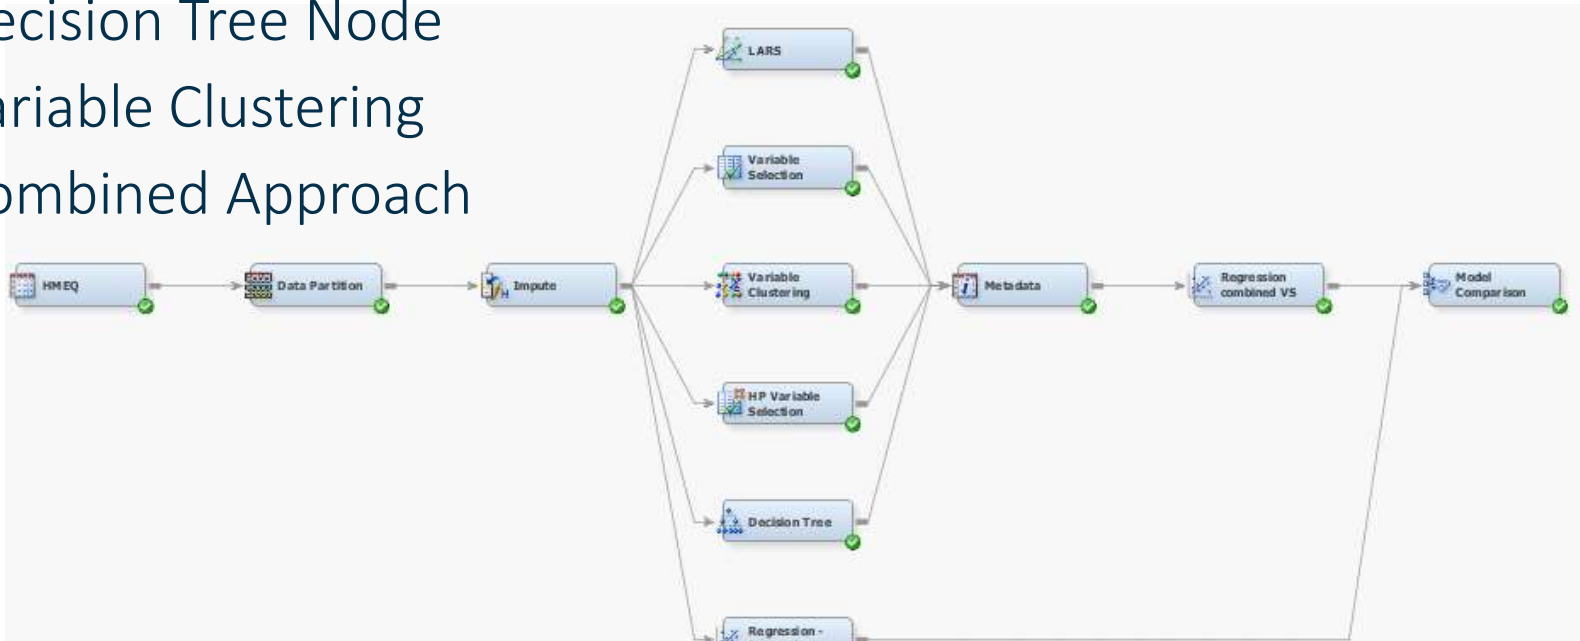

Selecting Variables

Explore & Modify

Variable Selection/Reduction Techniques

- Stepwise Regression
- Variable Selection Node
- Decision Tree Node
- Variable Clustering
- Combined Approach

Developing & Delivering the Model

Delivering the Model

- *Developing* Your Model
- *Choosing* a Model
- *Deploying* the Model

Developing the Model

MODEL

Model Development

- Regression
- Decision Trees
- Neural Networks
- Ensemble
- Random Forest
- Something Else?

BEST PRACTICE

Model Development

- Try various techniques and combinations of techniques.

Choosing a Model

Model Selection

- Evaluate model metrics
- Consider business knowledge
- Recognize constraints

How?

Model Selection Criteria

- Decisions/Assessment
 - Accuracy/Misclassification
 - *Profit/Loss*
 - *Inverse prior threshold*
- Estimates
 - Average squared error
 - SC (SBC or BIC)
- Rankings
 - ROC Index
 - Gini coefficients

Validation Fit Statistic Direction

Prediction Type	Validation Fit Statistic	Direction
Decisions	Misclassification	smallest
	Average Profit/Loss	largest/smallest
	Kolmogorov-Smirnov Statistic	largest
Rankings	ROC Index (concordance)	largest
	Gini Coefficient	largest
Estimates	Average Squared Error	smallest
	Schwarz's Bayesian Criterion	smallest
	Log-Likelihood	largest

Status	

The [Model Comparison](#) node provides a common framework for comparing models and predictions from any of the modeling tools (such as Regression, Decision Tree, and Neural Network tools). The comparison is based on standard model fits statistics as well as potential expected and actual profits or losses that would result from implementing the model. The node produces the following charts that help to describe the usefulness of the model: lift, profit, return on investment, receiver operating curves, diagnostic charts, and threshold-based charts.

- AIC Captured Response
- ASE KS Statistic
- MSE Misclassification
- ROC Average Profit/Loss
- Gain Cumulative Lift
- Lift Cumulative Captured Response
- Gini Cumulative Percent Response

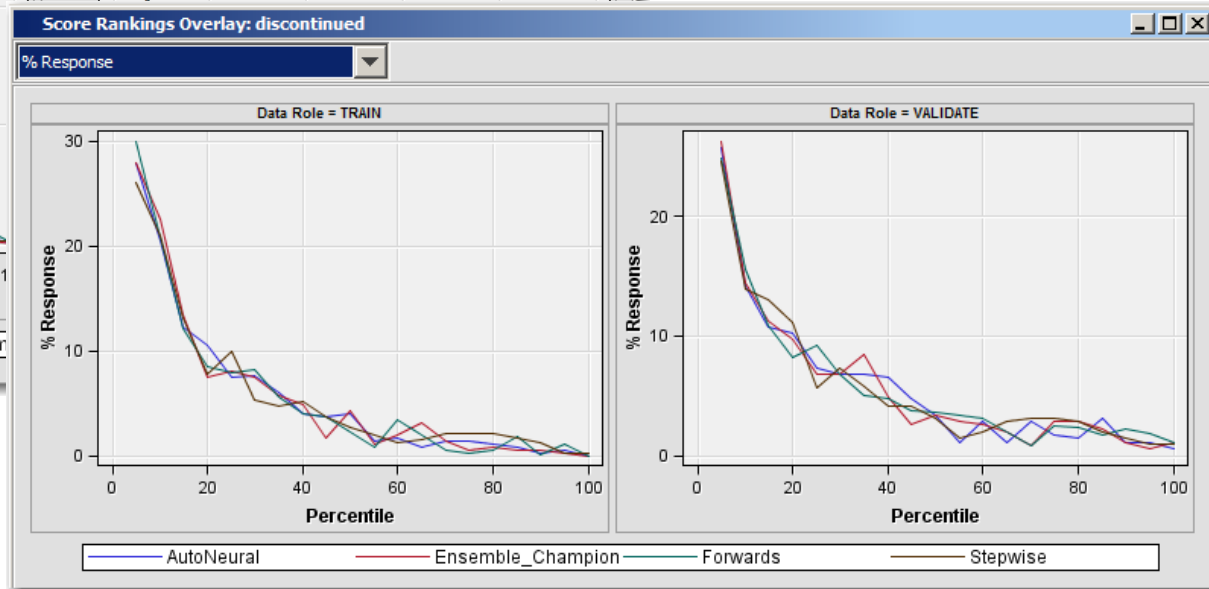

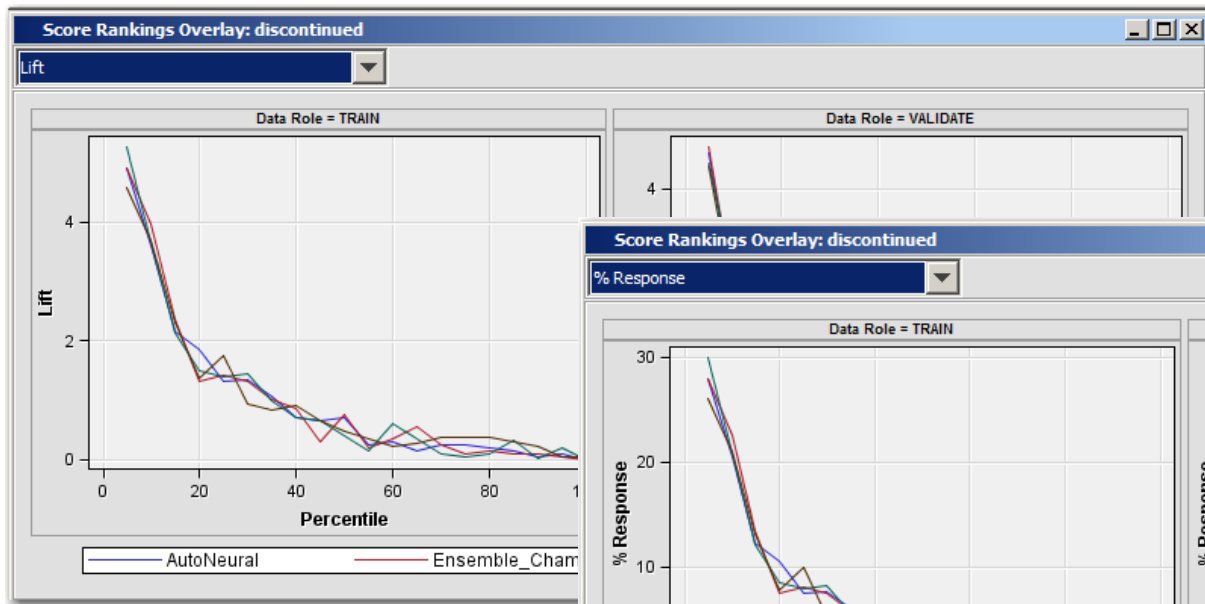

Available for training, validation
and test datasets
